

# Network Flow Applications

# Admin

- Assignment 6 is due next Wed
- Colloquium today: **3.15 pm**
  - Talk by Williams alum **Daniel Seita**
  - Currently a PhD at UC Berkeley
  - Works on robotic manipulation and machine learning
- Cool opportunity to hear about what students (like you) end up doing post Williams!
- Cool opportunity to find out what CS research looks like
  - Zoom link sent by Lauren

# Ford-Fulkerson Performance

**FORD-FULKERSON**( $G$ )

---

**FOREACH** edge  $e \in E : f(e) \leftarrow 0$ .

$G_f \leftarrow$  residual network of  $G$  with respect to flow  $f$ .

**WHILE** (there exists an  $s \rightarrow t$  path  $P$  in  $G_f$ )

$f \leftarrow$  **AUGMENT**( $f, P$ ).

Update  $G_f$ .

**RETURN**  $f$ .

- Does the algorithm terminate?
- Can we bound the number of iterations it does?
- Running time?

# Ford-Fulkerson Running Time

- Recall we proved that with each call to AUGMENT, we increase **value of flow** by  $b = \text{bottleneck}(G_f, P)$
- **Assumption.** Suppose all capacities  $c(e)$  are integers.
- **Integrality invariant.** Throughout Ford–Fulkerson, every edge flow  $f(e)$  and corresponding residual capacity is an integer. Thus  $b \geq 1$ .
- Let  $C = \max_u c(s \rightarrow u)$  be the maximum capacity among edges leaving the source  $s$ .
- It must be that  $v(f) \leq (n - 1)C$
- Since,  $v(f)$  increases by  $b \geq 1$  in each iteration, it follows that FF algorithm terminates in at most  $v(f) = O(nC)$  iterations.

# Ford-Fulkerson Performance

FORD-FULKERSON( $G$ )

FOREACH edge  $e \in E : f(e) \leftarrow 0$ .

$G_f \leftarrow$  residual network of  $G$  with respect to flow  $f$ .

WHILE (there exists an  $s \rightarrow t$  path  $P$  in  $G_f$ )

$f \leftarrow \text{AUGMENT}(f, P)$ .

Update  $G_f$ .

RETURN  $f$ .

- Operations in each iteration?
  - Find an augmenting path in  $G_f$
  - Augment flow on path
  - Update  $G_f$

# Ford-Fulkerson Running Time

- **Claim.** Ford-Fulkerson can be implemented to run in time  $O(nmC)$ , where  $m = |E| \geq n - 1$  and  $C = \max_u c(s \rightarrow u)$ .
- **Proof.** Time taken by each iteration:
  - Finding an augmenting path in  $G_f$ 
    - $G_f$  has at most  $2m$  edges, using BFS/DFS takes  $O(m + n) = O(m)$  time
  - Augmenting flow in  $P$  takes  $O(n)$  time
  - Given new flow, we can build new residual graph in  $O(m)$  time
  - Overall,  $O(m)$  time per iteration ■

# [Digging Deeper] Polynomial time?

- Does the Ford-Fulkerson algorithm run in time polynomial in the input size?
- Running time is  $O(nmC)$ , where  $C = \max_u c(s \rightarrow u)$
- What is the input size?
  - $n$  vertices,  $m$  edges,  $m$  capacities
  - $C$  represents the magnitude of the maximum capacity leaving the source node
  - How many bits to represent  $C$ ?
- Let us take an example

# [Digging Deeper] Polynomial time?

- **Question.** Does the Ford-Fulkerson algorithm run in polynomial-time in the size of the input?  $\longleftarrow \sim m, n, \text{ and } \log C$
- **Answer.** No. if max capacity is  $C$ , the algorithm can take  $\geq C$  iterations. Consider the following example.

- $s \rightarrow v \rightarrow w \rightarrow t$
- $s \rightarrow w \rightarrow v \rightarrow t$
- $s \rightarrow v \rightarrow w \rightarrow t$
- $s \rightarrow w \rightarrow v \rightarrow t$
- ...
- $s \rightarrow v \rightarrow w \rightarrow t$
- $s \rightarrow w \rightarrow v \rightarrow t$

$\longleftarrow$  each augmenting path  
sends only 1 unit of flow  
(# augmenting paths =  $2C$ )

# [Digger Deeper] Pseudo-Polynomial

- Input graph has  $n$  nodes and  $m = O(n^2)$  edges, each with capacity  $c_e$
- $C = \max_{e \in E} c(e)$ , then  $c(e)$  takes  $O(\log C)$  bits to represent
- Input size:  $\Omega(n \log n + m \log n + m \log C)$  bits
- Running time:  $O(nmC) = O(nm2^{\log C})$ 
  - Exponential in the *size* of  $C$
- Such algorithms are called **pseudo-polynomial**
  - If the running time is polynomial in the **magnitude** but **not size** of an input parameter.
  - We saw this for knapsack as well!

# Non-Integral Capacities?

- If the capacities are rational, can just multiply to obtain a large integer (massively increases running time)
- If capacities are irrational, Ford-Fulkerson can run infinitely!
  - Improvement at each step can be arbitrarily small
  - Can create bad instances where it doesn't terminate in finite steps

# Network Flow: Beyond Ford Fulkerson

# Edmond and Karp's Algorithms

- Ford and Fulkerson's algorithm does not specify which path in the residual graph to augment
- Poor worst-case behavior of the algorithm can be blamed on bad choices on augmenting path
- **Better choice of augmenting paths.** In 1970s, Jack Edmonds and Richard Karp published two natural rules for choosing augmenting paths
  - Widest path first: paths with largest bottleneck capacity
  - Shortest (in terms of edges) augmenting paths first (Dinitz independently discovered & analyzed this rule)

# Widest Augmenting Paths First

- Ford Fulkerson can be improved with a greedy algorithm way of choosing augmenting paths:
  - Choose the augmenting path with largest bottleneck capacity
- Largest bottleneck path can be computed in  $O(m \log n)$  time in a directed graph
  - Similar to Dijkstra's analysis
- How many iterations if we use this rule?
  - Won't prove this: but takes  $O(m \log C)$  iterations
- Overall running time is  $O(m^2 \log n \log C)$  (polynomial time!)
  - Still depends on  $C$  though

# Shortest Augmenting Paths First

- Choose the augmenting path with the smallest # of edges
- Can be found using BFS on  $G_f$  in  $O(m + n) = O(m)$  time
- Surprisingly, this resulting a polynomial-time algorithm independent of the actual edge capacities !
- Analysis looks at “level” of vertices in the BFS tree of  $G_f$  rooted at  $s$  —levels only grow over time
- Analyzes # of times an edge  $u \rightarrow v$  disappears from  $G_f$
- Takes  $O(mn)$  iterations overall
- Thus overall running time is  $O(m^2n)$

# Progress on Network Flows

1951	$O(m n^2 C)$	Dantzig
1955	$O(m n C)$	Ford–Fulkerson
1970	$O(m n^2)$	Edmonds–Karp, Dinitz
1974	$O(n^3)$	Karzanov
1983	$O(m n \log n)$	Sleator–Tarjan
1985	$O(m n \log C)$	Gabow
1988	$O(m n \log (n^2 / m))$	Goldberg–Tarjan
1998	$O(m^{3/2} \log (n^2 / m) \log C)$	Goldberg–Rao
2013	$O(m n)$	Orlin
2014	$\tilde{O}(m n^{1/2} \log C)$	Lee–Sidford
2016	$\tilde{O}(m^{10/7} C^{1/7})$	Mądry
2017	$\tilde{O}(m^{10/7} \log W)$	Cohen–Mądry

For unit capacity networks

# Progress on Network Flows

- Best known:  $O(nm)$
- Best lower bound?
  - None known. (Needs  $\Omega(n + m)$  just to look at the network, but that's it)
- Some of these algorithms do REALLY well in “practice;” basically  $O(n + m)$
- Well-known open problem

# Applications of Network Flow:

Solving Problems by  
Reduction to Network Flows

# Max-Flow Min-Cut Applications

- Data mining
- Bipartite matching
- Network reliability
- Image segmentation
- Baseball elimination
- Network connectivity
- Markov random fields
- Distributed computing
- Network intrusion detection
- **Many, many, more.**

liver and hepatic vascularization segmentation

# Max-Flow Min-Cut Applications

- **Network flows** model a variety of optimization problems
- These optimization problems look complicated with lots of constraints; on the face of it seem to have nothing to do with networks or flows

**Clients to base stations.** Consider a set of mobile computing clients who each need to be connected to one of several possible base stations. We'll suppose there are  $n$  clients and  $k$  base stations; the position of each of these is specified by their  $(x, y)$  coordinates in the plane.

For each client, we wish to connect it to exactly one of the base stations, constrained in the following ways: a client can only be connected to a base station that is within distance  $r$ , and no more than  $L$  clients can be connected to any single base station. Design a polynomial time algorithm for the problem.

# Max-Flow Min-Cut Applications

- **Network flows** model a variety of optimization problems
- These optimization problems look complicated with lots of constraints; on the face of it seem to have nothing to do with networks or flows

**Survey design:** Design survey asking  $n_1$  consumers about  $n_2$  products.

- Can survey consumer  $i$  about product  $j$  only if they own it.
- Ask consumer  $i$  between  $c_i$  and  $c'_i$  questions.
- Ask between  $p_j$  and  $p'_j$  consumers about product  $j$ .

**Goal.** Design a survey that meets these specs, if possible.

# Max-Flow Min-Cut Applications

- **Network flows** model a variety of optimization problems
- These optimization problems look complicated with lots of constraints; on the face of it seem to have nothing to do with networks or flows

**Airline scheduling:** A very complicated scheduling problem but we can turn it into a simplified one:

Every day we have  $k$  flights and flight  $i$  leaves origin  $o_i$  at time  $s_i$  and arrives at destination  $d_i$  at time  $f_i$ .

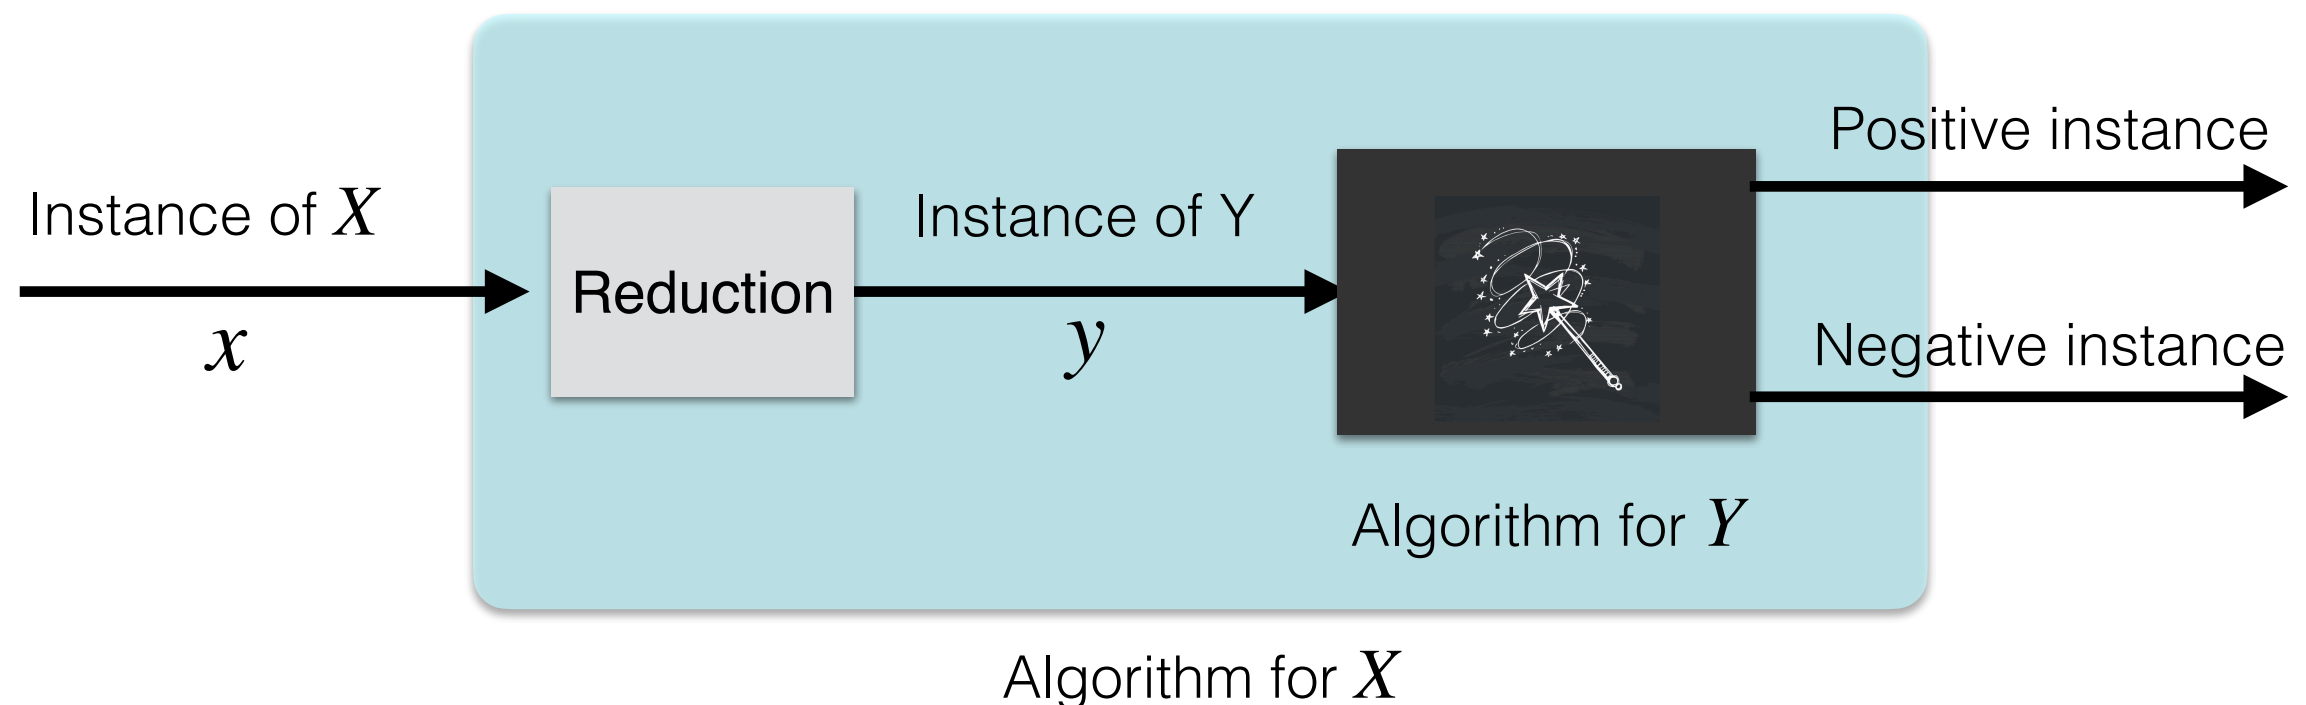

**Goal.** Minimize number of flight crews.

# Reductions

- We will solve all these problems by reducing them to a network flow problem
- We'll focus on the concept of **problem reductions**

# Anatomy of Problem Reductions

- At a high level, a problem  $X$  reduces to a problem  $Y$  if an algorithm for  $Y$  can be used to solve  $X$
- **Reduction.** Convert an arbitrary instance  $x$  of  $X$  to a special instance  $y$  of  $Y$  such that there is a 1-1 correspondence between them

# Anatomy of Problem Reductions

- **Claim.**  $x$  satisfies a property iff  $y$  satisfies a corresponding property
- Proving a reduction is correct: prove both directions
- $x$  has a property (e.g. has matching of size  $k$ )  $\implies y$  has a corresponding property (e.g. has a flow of value  $k$ )
- $x$  does not have a property (e.g. does not have matching of size  $k$ )  $\implies y$  does not have a corresponding property (e.g. does not have a flow of value  $k$ )
- Or equivalently (and this is often easier to prove):
  - $y$  has a property (e.g. has flow of value  $k$ )  $\implies x$  has a corresponding property (e.g. has a matching of value  $k$ )

# Today's Plan

- We will explore one application of network flow in detail today
  - Matching in bipartite graphs
  - Matchings are super practical have many applications
  - We have already seen one, can you remember?
- Next lecture: more applications of network flow
  - More practice with reductions
  - We will do some in-class exercises of reductions next time

# Bipartite Matching

# Review: Matching in Graphs

- **Definition.** Given an undirected graph  $G = (V, E)$ , a matching  $M \subseteq E$  of  $G$  is a subset of edges such that no two edges in  $M$  are incident on the same vertex.

# Review: Matching in Graphs

- **Definition.** Given an undirected graph  $G = (V, E)$ , a matching  $M \subseteq E$  of  $G$  is a subset of edges such that no two edges in  $M$  are incident on the same vertex.
  - In other words, each node appears in at most one edge in  $M$
- A perfect matching matches all nodes in  $G$
- **Max matching problem.** Find a matching of maximum cardinality for a given graph, that is, a matching with maximum number of edges
  - A perfect matching if it exists is maximum!

# Review: Bipartite Graphs

- A graph is **bipartite** if its vertices can be partitioned into two subsets  $X, Y$  such that every edge  $e = (u, v)$  connects  $u \in X$  and  $v \in Y$
- **Bipartite matching problem.** Given a bipartite graph  $G = (X \cup Y, E)$  find a maximum matching.

# Bipartite Matching Examples

- Models many assignment problems
  - $A$  is a set of jobs,  $B$  as a set of machines
  - Edge  $(a_i, b_j)$  indicates where machine  $b_j$  is able to process job  $a_i$
  - Perfect matching: way to assign each job to a machine that can process it, such that, each machine is assigned exactly one job
- Assigning customers to stores, students to dorms, etc
- **Note.** This is a different problem than the one we studied for Gale-Shapely matching!

# Maximum & Perfect Matchings

- One of the oldest problems in combinatorial algorithms:
  - Determine the largest matching in a bipartite graph
- This doesn't seem like a network flow problem
  - But we will turn it into one
- Special case: Find a perfect matching in  $G$  if it exists
  - What conditions do we need for perfect matching?
  - Certainly need  $|A| = |B|$
  - What are the necessary and sufficient conditions?
  - Will use network flow to determine

# Reduction to Max Flow

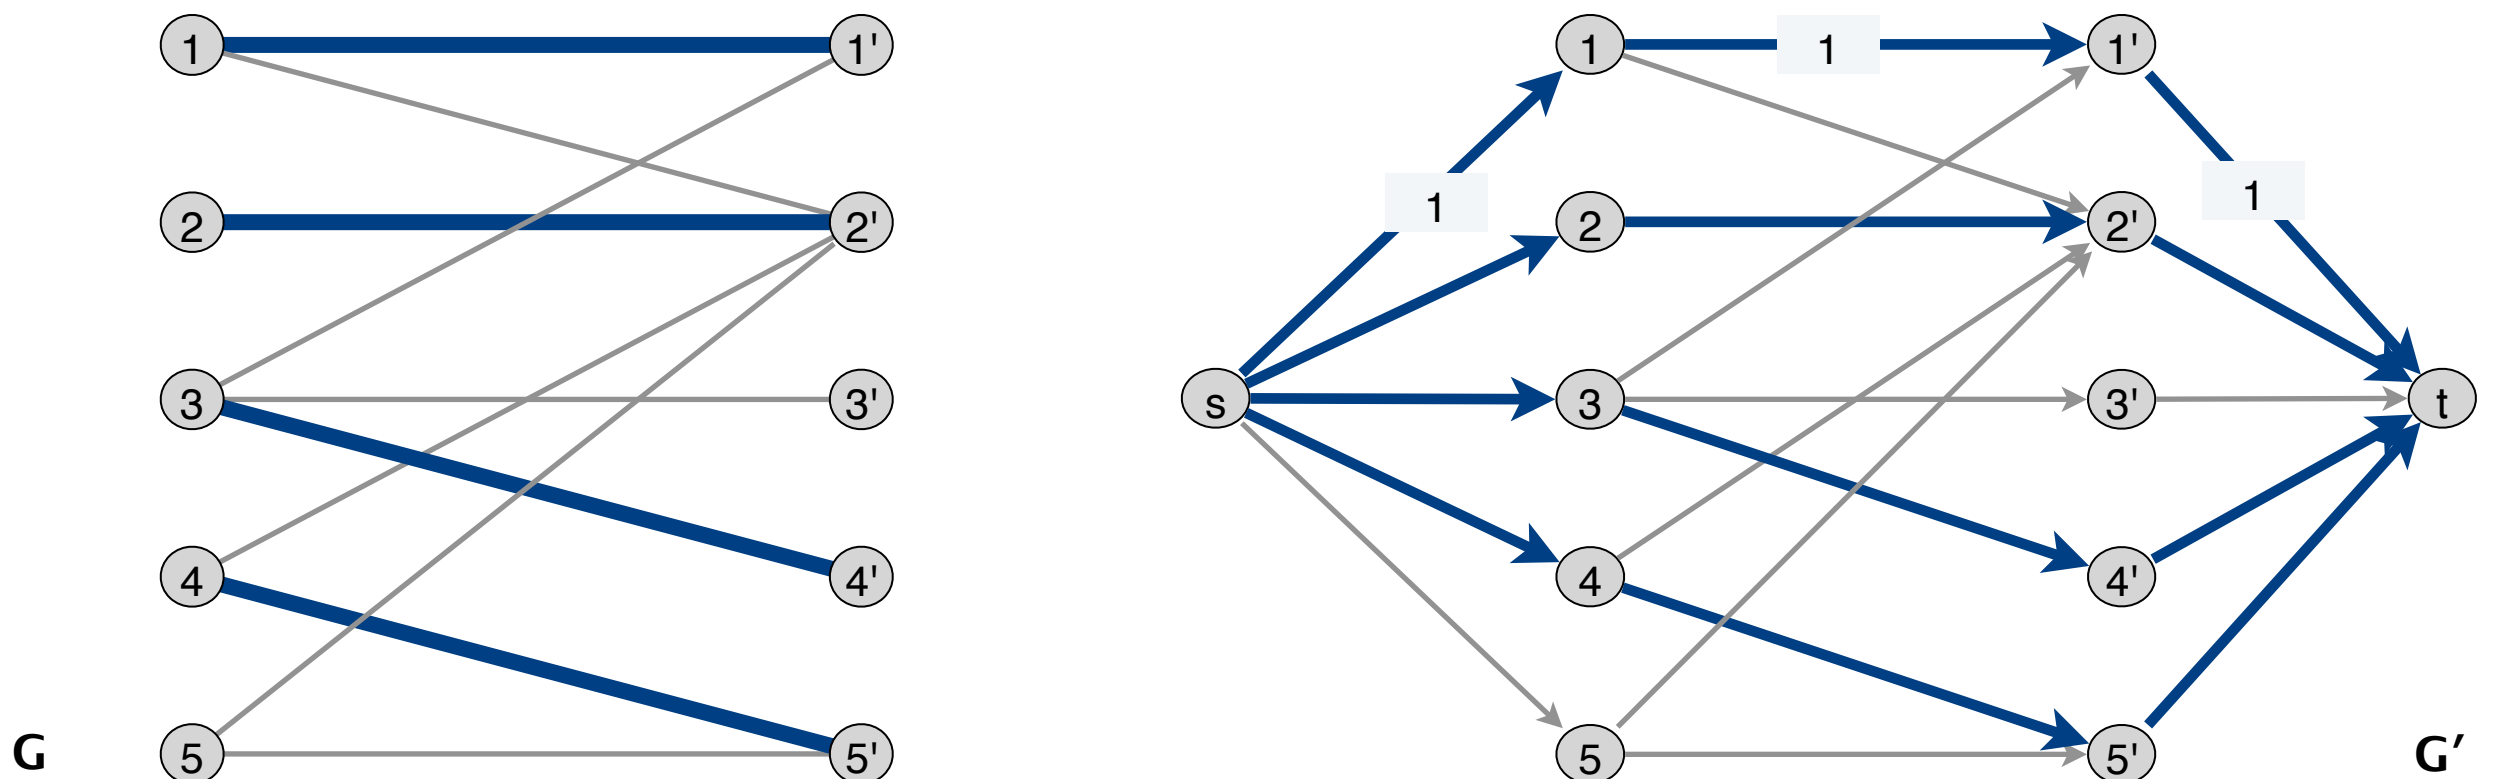

- Given arbitrary instance  $x$  of bipartite matching problem  $(X)$ :  $A, B$  and edges  $E$  between  $A$  and  $B$
- **Goal.** Create a special instance  $y$  of a max-flow problem  $(Y)$ : flow network:  $G(V, E, c)$ , source  $s$ , sink  $t \in V$  s.t.
- **1-1 correspondence.** There exists a matching of size  $k$  iff there is a flow of value  $k$

# Reduction to Max Flow

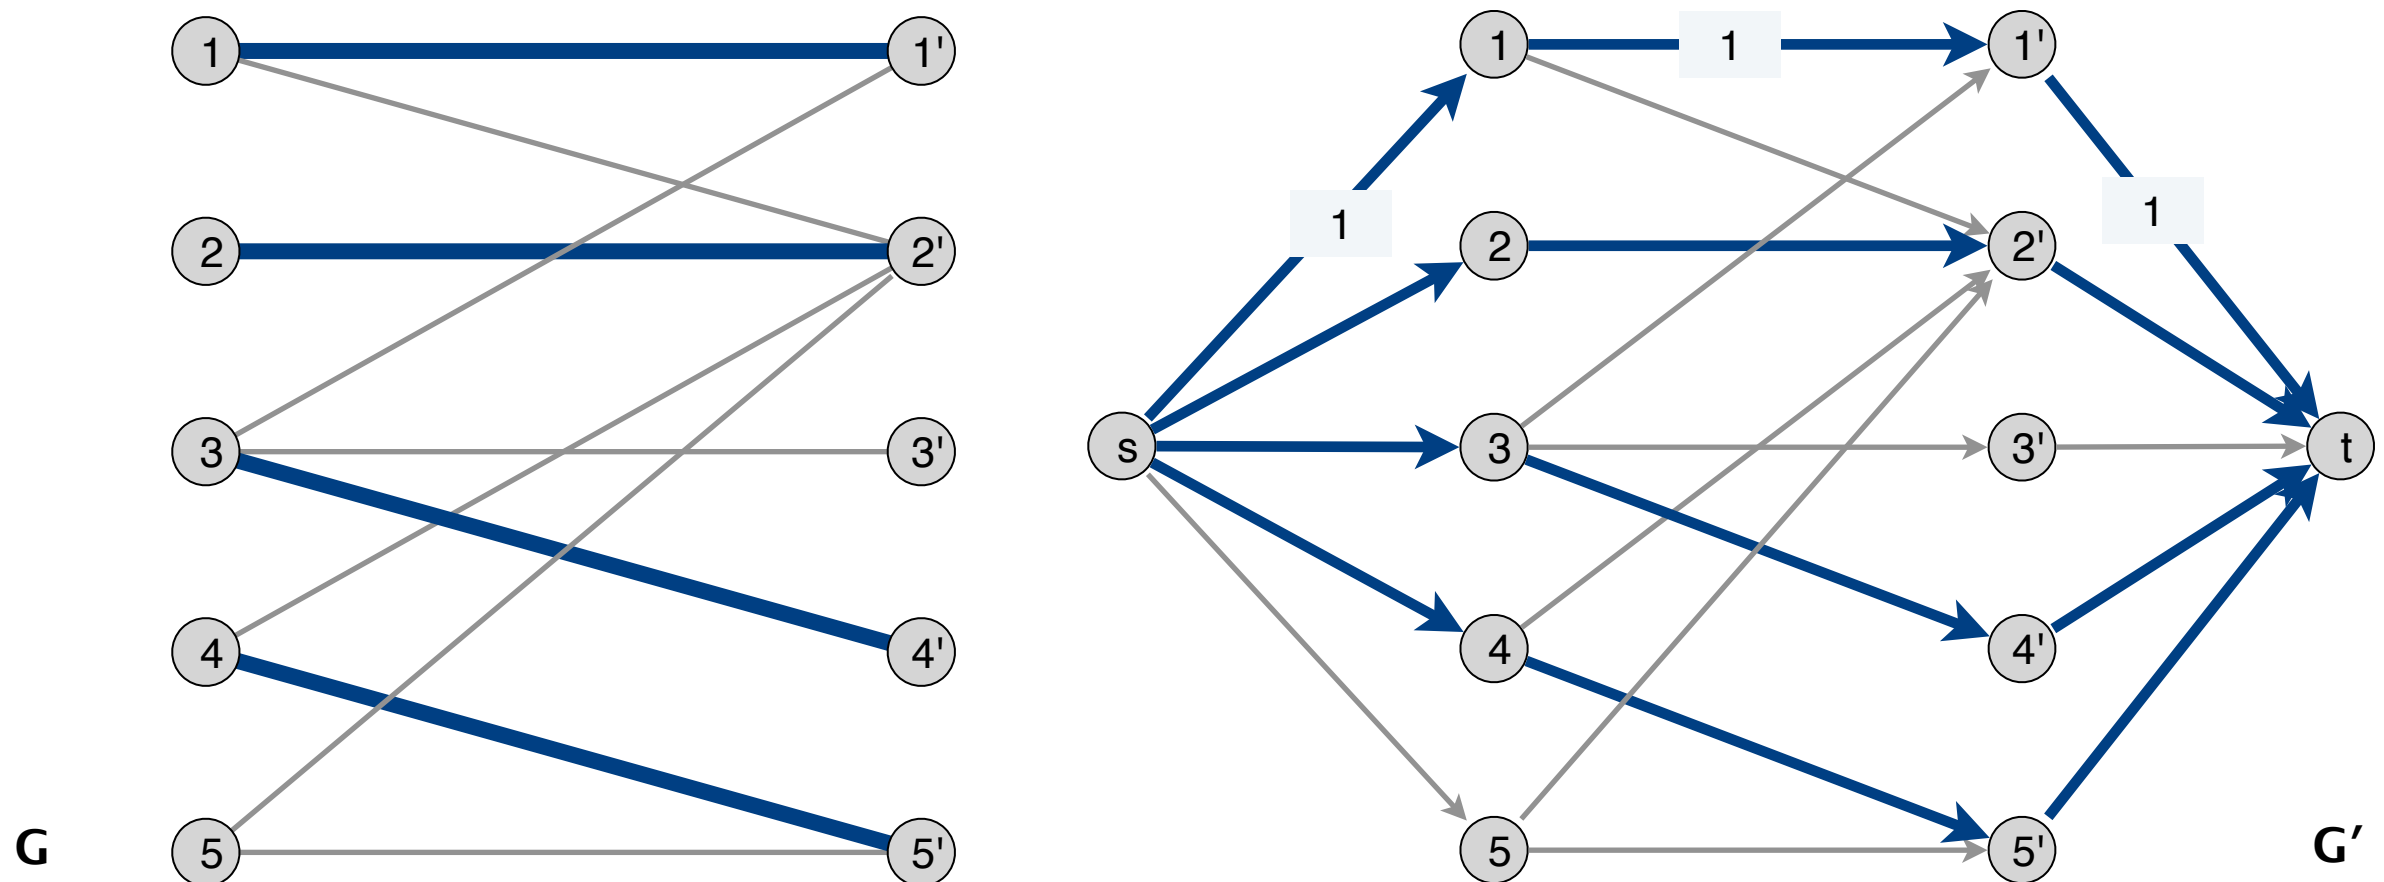

- Create a new directed graph  $G' = (A \cup B \cup \{s, t\}, E', c)$
- Add edge  $s \rightarrow a$  to  $E'$  for all nodes  $a \in A$
- Add edge  $b \rightarrow t$  to  $E'$  for all nodes  $b \in B$
- Direct edge  $a \rightarrow b$  in  $E'$  if  $(a, b) \in E$
- Set capacity of all edges in  $E'$  to 1

# Correctness of Reduction

- **Claim** ( $\Rightarrow$ ).

If the bipartite graph  $(A, B, E)$  has matching  $M$  of size  $k$  then flow-network  $G'$  has an integral flow of value  $k$ .

# Correctness of Reduction

- **Claim** (  $\Rightarrow$  ).

If the bipartite graph  $(A, B, E)$  has matching  $M$  of size  $k$  then flow-network  $G'$  has an integral flow of value  $k$ .

- **Proof.**

- For every edge  $e = (a, b) \in M$ , let  $f$  be the flow resulting from sending 1 unit of flow along the path  $s \rightarrow a \rightarrow b \rightarrow t$
- $f$  is a feasible flow (satisfies capacity and conservation) and integral
- $v(f) = k$

# Correctness of Reduction

- **Claim** ( $\Rightarrow$ ).

If the bipartite graph  $(A, B, E)$  has matching  $M$  of size  $k$  then flow-network  $G'$  has an integral flow of value  $k$ .

**G**

**G'**

# Correctness of Reduction

- **Claim** ( $\Leftarrow$ ).

If flow-network  $G'$  has an integral flow of value  $k$ , then the bipartite graph  $(A, B, E)$  has matching  $M$  of size  $k$ .

# Correctness of Reduction

- **Claim** (  $\Leftarrow$  ).

If flow-network  $G'$  has an integral flow of value  $k$ , then the bipartite graph  $(A, B, E)$  has matching  $M$  of size  $k$ .

- **Proof.**

- Let  $M =$  set of edges from  $A$  to  $B$  with  $f(e) = 1$ .
- No two edges in  $M$  share a vertex, why?
- $|M| = k$ 
  - $v(f) = f_{out}(S) - f_{in}(S)$  for any  $(S, V - S)$  cut
  - Let  $S = A \cup \{s\}$

# Correctness of Reduction

- **Claim** ( $\Leftarrow$ ).

If flow-network  $G'$  has an integral flow of value  $k$ , then the bipartite graph  $(A, B, E)$  has matching  $M$  of size  $k$ .

# Summary & Running Time

- Proved matching of size  $k$  iff flow of value  $k$
- Thus, max-flow iff max matching
- Running time of algorithm overall:
  - Running time of reduction + running time of solving the flow problem (dominates)
- What is running time of Ford–Fulkerson algorithm for a flow network with all unit capacities?
  - $O(nm)$
- Overall running time of finding max-cardinality bipartite matching:  $O(nm)$

# Understanding Bipartite Matchings Better

# Perfect Matchings

- Suppose we want a perfect matching: a matching that matches all vertices
- If the maximum matching produced by our algorithm has size  $n = |A| = |B|$ : we know we have a perfect matching
- Suppose the maximum matching produced is smaller
  - How can we give a certificate that shows it is impossible to find a perfect matching in such a graph?
- Let's think about necessary and sufficient conditions for a graph to have a perfect matching

# Aside: Necessary & Sufficient

Suppose  $P \implies Q$  (If  $P$ , then  $Q$ )

- We say  $Q$  is necessary for  $P$ 
  - In other words, it is impossible to have  $P$  without  $Q$
- Similarly, we say  $P$  is sufficient for  $Q$ 
  - $P$  being true, implies  $Q$  is true
  - But if  $P$  is false, we can't say anything about  $Q$
- Necessary and sufficient conditions:
  - $P \iff Q$ , if and only if characterization

# Perfect Matchings

- **Notation.** Let  $S$  be a subset of nodes in  $G$ , and let  $N(S)$  be the set of nodes adjacent to nodes in  $S$  in  $G$ .
- **[Halls marriage theorem.]** Let  $G = (X \cup Y, E)$  be a bipartite graph with  $|X| = |Y|$ . Then, graph  $G$  has a perfect matching iff  $|N(S)| \geq |S|$  for all subsets  $S \subseteq L$ .
- Proof.
- $(\Rightarrow)$ . In a perfect matching, each node in  $S$  needs to be matched with a different node in  $N(S)$
- $(\Leftarrow)$ . Suppose  $G$  does not have a perfect matching
- In our max-flow problem, this means max flow is less than  $n$

# Perfect Matchings & Cuts

- ( $\Leftarrow$ ). Suppose  $G$  does not have a perfect matching
- The capacity of the min-cut  $(A', B')$  is less than  $n$
- $A'$  may contain nodes from both  $X$  and  $Y$

# Perfect Matchings & Cuts

- $A'$  may contain nodes from both  $X$  and  $Y$ 
  - We want a subset  $A$ , s.t.  $|N(A)| \leq |A|$
- Claim.  $A = X \cap A'$  has this property.

# Perfect Matchings & Cuts

- Claim.  $A = X \cap A'$  has the property that  $|N(A)| \leq |A|$

# Perfect Matchings & Cuts

- Cases:  $N(A) \subseteq A'$  or  $N(A) \not\subseteq A'$

$N(A) \not\subseteq A'$

$N(A) \subseteq A'$

# Perfect Matchings & Cuts

- We will show, if a mincut  $(A', B')$  doesn't have the property that  $N(A) \subseteq A'$ , we can find a new cut that does, that is, wlog we can assume  $N(A) \subseteq A'$ , where  $A = X \cap A'$

$$N(A) \not\subseteq A'$$

$$N(A) \subseteq A'$$

# Perfect Matchings & Cuts

- Pick an edge  $(x, y)$  s.t.  $x \in A$  and  $y \notin A'$
- **Claim:** moving  $y$  to  $A'$  doesn't increase capacity of the cut

$$N(A) \not\subseteq A'$$

$$N(A) \subseteq A'$$

# Perfect Matchings & Cuts

- Now wlog, assume  $N(A) \subseteq A'$
- $c(A', B')$  = capacity of edges that leave the source to nodes in  $X$  outside  $A'$  + capacity of edges from nodes in  $Y$  and  $A'$  to the sink

# Perfect Matchings & Cuts

- Now wlog, assume  $N(A) \subseteq A'$
- $c(A', B') = |X \cap B'| + |Y \cap A'|$
- Now,  $|X \cap B'| = n - |A|$  and  $|Y \cap A'| \geq |N(A)|$

# Perfect Matchings & Cuts

- Now wlog, assume  $N(A) \subseteq A'$
- $c(A', B') = |X \cap B'| + |Y \cap A'|$
- $n - |A| + |N(A)| \leq c(A', B')$

# Perfect Matchings & Cuts

- Now wlog, assume  $N(A) \subseteq A'$
- $c(A', B') = |X \cap B'| + |Y \cap A'|$
- $n - |A| + |N(A)| \leq c(A', B') < n$

# Perfect Matchings & Cuts

- Now wlog, assume  $N(A) \subseteq A'$
- $c(A', B') = |X \cap B'| + |Y \cap A'|$
- $|N(A)| < |A|$  ■

# Summary: Flows and Matching

- We have proved Hall's theorem using network flows!
- **[Halls marriage theorem.]** Let  $G = (X \cup Y, E)$  be a bipartite graph with  $|X| = |Y|$ . Then, graph  $G$  has a perfect matching iff  $|N(S)| \geq |S|$  for all subsets  $S \subseteq L$ .
- If  $G$  has a perfect matching, we can find one using flow!
- If  $G$  doesn't have a perfect matching, we can find a certificate for this: a subset of nodes that violate Hall's condition!
- **Takeaway.** Algorithms can be useful in proving purely combinatorial math theorems!
